## 8. Homework

1) Compile and run mysh.c in section 5. What is the difference between mysh and the system shell(the login shell that runs when you log in)? Show at least 5 differences.

```
kyumin@DESKTOP-NUDFAPK ~  
$ mysh  
$pwd  
I am child to execute pwd  
exec failed: No such file or directory  
$
```

```
kyumin@DESKTOP-NUDFAPK ~  
$ mysh  
$/bin/ls  
I am child to execute /bin/ls  
cdssetup  ex2.c  ex7.c  f3          mycat3.c  myxxd.c  
d1         ex2.exe ex7.exe f8          mycat3.exe myxxd.exe  
d2         ex3.c  ex8.c  hw4.c      mycp.c    newhw4  
digitfile  ex3.exe  ex8.exe hw4.exe    mycp.exe  newhw4.c  
ex0.c      ex4.c  ex9.c  midexam.c  myecho.c  sw2.wav  
ex0.exe    ex4.exe ex9.exe midexam.exe myecho.exe swvader03.wav  
ex1.c      ex5.c  exam.c  mycat.c    myexec.c  x  
ex1.exe    ex5.exe exdir   mycat.exe  myexec.exe  
ex10.c     ex6.c  f1      mycat2.c   mysh.c  
ex10.exe   ex6.exe f2      mycat2.exe mysh.exe  
$
```

1. 명령어만 입력 시 오류가 발생한다.
2. /bin/ls 형태로 입력해야 작동한다.
3. 10번까지만 명령어를 실행할 수 있다.
4. 명령어 실행 시 자식이 실행했다는 메시지가 뜬다.
5. Argument가 두 개 이상 들어갈 수 없다.

2) What is the process name of your login shell? What is the executable file name of your login shell and how can you find it? Who is the parent of your login shell? Explain how the parent of your login shell can create your login shell by showing its C code(roughly). Find all ancestor processes of your login shell.

```
kyumin@DESKTOP-NUDFAPK ~
$ ps
  PID   PPID   PGID   WINPID   TTY        UID     STIME  COMMAND
  950     949    950    15580   pty0       197609  09:17:20 /usr/bin/bash
  949        1    949    31528   ?          197609  09:17:20 /usr/bin/mintty
  988    950    988    24788   pty0       197609  09:30:42 /usr/bin/ps

kyumin@DESKTOP-NUDFAPK ~
$ mysh
$/bin/ps
I am child to execute /bin/ps
  PID   PPID   PGID   WINPID   TTY        UID     STIME  COMMAND
  950     949    950    15580   pty0       197609  09:17:20 /usr/bin/bash
  992    950    992    30232   pty0       197609  09:32:41 /cygdrive/c/User
s/kyumin/AppData/Roaming/SPB_Data/mysh
  949        1    949    31528   ?          197609  09:17:20 /usr/bin/mintty
  993    992    992    19612   pty0       197609  09:32:44 /usr/bin/ps
$
```

로그인 쉘의 프로세스 이름은 “pty0”이고, 파일명은 bash이며, /usr/bin/bash에 있다.

로그인 쉘의 부모의 pid는 949이고, 이름은 보이지 않고 “?”로 나타난다.

Mysh를 실행하고 ps 명령어로 프로세스를 확인해봤다. Mysh 프로세스의 pid는 992다.

Mysh의 부모 pid는 950이다.

3) (Builtin Command) Improve mysh such that it exits when the user types "exit". You have to handle “exit” before “fork”. Explain why. This kind of commands that the shell has to handle before fork are called built-in commands.

```

void main(){
    int x,y,status, i;
    char buf[50];
    char * argv[10];

    for(i=0;i<10;i++){ // use a finite loop instead of an infinite loop
        printf("$");
        scanf("%s", buf); // get command.
        if(strcmp(buf, "exit") == 0) exit(0);

        argv[0]=buf;
        argv[1]=0;

        x=fork();
        if (x==0){ // child
            printf("I am child to execute %s\n", buf);
            y=execve(buf, argv, 0);
            if (y<0){
                perror("exec failed");
                exit(1);
            }
        }
        else wait(&status);
    }
}

```

Fork를 하고 자식 프로세스가 exit을 하면 자식만 바다가 삭제되고, 부모 프로세스는 삭제되지 않는다. 그래서 부모의 코드에서 exit을 해줘야한다. 그래서 위의 코드처럼 fork를 하기 전 부모 프로세스에서 exit이 입력된다면 exit을하도록 코드를 작성하였다.

```

kyumin@DESKTOP-NUDFAPK ~
$ mysh
$/bin/pwd
I am child to execute /bin/pwd
/cygdrive/c/Users/kyumin/AppData/Roaming/SPB_Data
$exit

```

Exit을 입력한다면 정상적으로 프로그램이 종료된다.

4) Improve mysh further such that it can handle a command with arguments, such as "/bin/ls -l". Use gets() or fgets() to read the command.

```

void main(){
    int x,y,status, i;
    char buf[50];
    char * argv[10];

    for(i=0;i<10;i++){ // use a finite loop instead of an infin
        printf("$");
        //scanf("%s", buf); // get command.
        fgets(buf, 50, stdin);
        buf[strlen(buf) - 1] = '\0';

        argv[0] = strtok(buf, " ");
        if(strcmp(argv[0], "exit") == 0) exit(0);

        for(int i = 1;i< strlen(buf); i++)
        {
            argv[i] = strtok(NULL, " ");
            if(argv[i] == NULL) break;
        }

        x=fork();
        if (x==0){ // child
            printf("I am child to execute %s\n", buf);
            y=execve(argv[0], argv, 0);
            if (y < 0){
                perror("exec failed");
                exit(1);
            }
        }
        else wait(&status);
    }
}

```

우선 여러 argument 를 받기 위해선 여러 단어를 입력 받을 수 있어야한다. Scanf 의 경우 단어 하나만 입력받기 때문에 띄어쓰기가 입력되면 앞 단어만 읽는다.

그래서 fgets 를 사용했고, 이 함수는 입력 시 Enter 를 줄바꿈으로 읽기 때문에 마지막 글자를 ‘\0’으로 바꿨다. 그리고 strtok 함수를 사용해서 여러 단어가 입력되면 토큰을 나누고, 그 토큰을 argv 배열에 따로 저장하였다. 그리고 execve 함수의 argument 로 argv 를 사용했다.

```

kyumin@DESKTOP-NUDFAPK ~
$ mysh
$/bin/ls -l
I am child to execute /bin/ls
total 1675
drwx-----+ 1 kyumin 2월 0  Mar 15  2021 cdssetup
drwxr-xr-x+ 1 kyumin 2월 0  Apr 14 15:45 d1
drwxr-xr-x+ 1 kyumin 2월 0  Mar  6 12:47 d2
-rwxr-xr-x+ 1 kyumin 2월 1  Apr 18 23:21 digitfile

-rwxr-xr-x+ 1 kyumin 2월 68716 Apr 18 23:21 ex10.exe

```

수정된 프로그램으로 실행해보면 단순히 ls 명령어가 실행된게 아니라 -l 옵션으로 실행이 된 것을 볼 수 있다.

4-1) Improve it further so that it can handle "cd" comand. Also improve it so that it can handle "pwd" command. Note “cd” and “pwd” are other examples of built-in command.

```

void main(){
    int x,y,status, i;
    char buf[50];
    char * argv[10];

    for(i=0;i<10;i++){ // use a finite loop instead of an infinite loop
        printf("$");
        fgets(buf, 50, stdin);
        buf[strlen(buf) - 1] = '\0';

        argv[0] = strtok(buf, " ");
        if(strcmp(argv[0], "exit") == 0) exit(0);
        else if(strcmp(argv[0], "cd") == 0)
        {
            argv[1] = strtok(NULL, " ");
            chdir(argv[1]);
        }

        else
        {
            for(int i = 1; i < strlen(buf); i++)
            {
                argv[i] = strtok(NULL, " ");
                if(argv[i] == NULL) break;
            }
        }

        x=fork();
        if (x==0){ // child
            printf("I am child to execute %s\n", buf);
            y=execve(argv[0], argv, 0);
            if (y < 0){
                perror("exec failed");
                exit(1);
            }
        }
        else wait(&status);
    }
}

```

```

kyumin@DESKTOP-NUDFAPK ~
$ mysh
$cd dl
I am child to execute cd
exec failed: No such file or directory
$/bin/ls
I am child to execute /bin/ls
f3
$|

```

5) (Handling &) Change the shell such that it can handle '&' at the end of the command.

```
$ ex1
```

In above, the shell waits until ex1 (the child) is finished. You should make ex1 to have an infinite loop to see the effect.

```
$ ex1 &
```

In above, the shell does not wait and immediately prints the next prompt and waits for the next user command. Make sure you delete "&" at the end of the command once you detect it.

6) (Handling relative path) Make your shell handle relative paths assuming the executable file always exists in /bin directory. When the user enters only the command name (e.g. "ls -l", "cp f1 f2", etc), build a full path such as "/bin/ls", "/bin/cp", etc. and perform exec. Use sprintf() to build the full path.

6-1) Use getenv("PATH") to retrieve PATH environment variable and use strtok() to extract each system path. Display each system path line by line.

```
    /usr/lib64/ccache
```

```
    /usr/local/bin
```

```
    /usr/bin
```

```
    .....
```

7) (Handling relative path) Change the shell such that it can handle relative path for the command in general. The shell will search the PATH environment variable to compute the full path of the command when it is given as a relative path name. Use getenv("PATH") to obtain the pointer to the value of the PATH environment variable. Note you need to copy the string of the PATH variable into another char array before you start extracting each path component with strtok() since strtok() destroys the original string.

8) dup(x) duplicates fd[x] in the first empty entry in the fd table. Run following program and explain the output. Assume f1 has

```
    hello my boy
```

```
x=open("f1", O_RDONLY, 00777);
```

```
int y;
```

```
y=dup(x);
```

```
printf("x:%d y:%d\n", x, y);
```

```
char buf[50];
```

```
int k=read(x, buf, 5);
```

```
buf[k]=0;
```

```
printf("buf:%s\n", buf);
```

```
k=read(y, buf, 5);  
buf[k]=0;  
printf("buf:%s\n", buf);
```

9) (Standard output redirection) Explain the output of the following code.

```
x=open("f2", O_WRONLY|O_CREAT|O_TRUNC,00777);  
printf("x:%d\n", x);  
int y;  
close(1);  
y=dup(x);  
printf("x:%d y:%d\n", x, y);  
write(1, "hi there", 8);
```

10) (Standard output redirection) Change the shell such that it can handle standard output redirection.

```
$ cat f1 > f3
```

will redirect the output of "cat f1" to file f3.
